1, Explain behaviour of hub device

HUD is used to connect the computer and to form a LAN network. HUB will do direct broadcast for sharing the date to all connected devices. Due to this high traffic and loss of data is occurred.

2 , Explain behaviour of switch device

To overcome HUB problem, they have developed Switch. Switch will do both unicast and broadcast. When we use ping command we will not know the destination MAC address, so by send the request first switch will make a table and store the MAC of this is present in the request if destination MAC address was already present in table it will do unicast and send the file accordingly. In case, destination MAC address was not found in that table, the ARP will send the request and Switch will send the request to all the network IP's which is present in that network this is called broadcast. So switch will do broadcast when destination MAC is not found in the table. ARP request is to the all IP's, the destination IP will be present in the request so that IP will reply to that request and send the MAC address as a reply to the sender mac and IP, this reply will receive to the switch, here switch will store that MAC address in that table and look for destination MAC, which is already present in that table it will do unicast. This table will be store the MAC only for 5mins.

3 , Explain behaviour of router device

Like switch, Router will also have one table called route table in that Network ID and prefix length and port name will be present. Once the request reaches the router it will check the network ID of the given IP in the request, if the network ID was not found in that table it will cut the connection. In case the network ID was found in that table it will send the request to that mentioned route.
